

Abstract

[0129] Thus, as shown by an exact electrodynamic
computation of EMBF and the estimations described above
of the velocity of turbulent flows arising due to their
5 effect, application of amplitude- and frequency-
modulated helically traveling (rotating and axially
traveling) electromagnetic fields in metallurgical and
chemical technologies and foundry can considerably
increase the hydraulic efficiency of MHD facilities,
10 intensify the processes of heat and mass transfer in
technological plants, significantly increase their
productivity, considerably decrease energy consumption
for the production of metals, alloys, cast articles,
and chemical products, and improve their quality.
